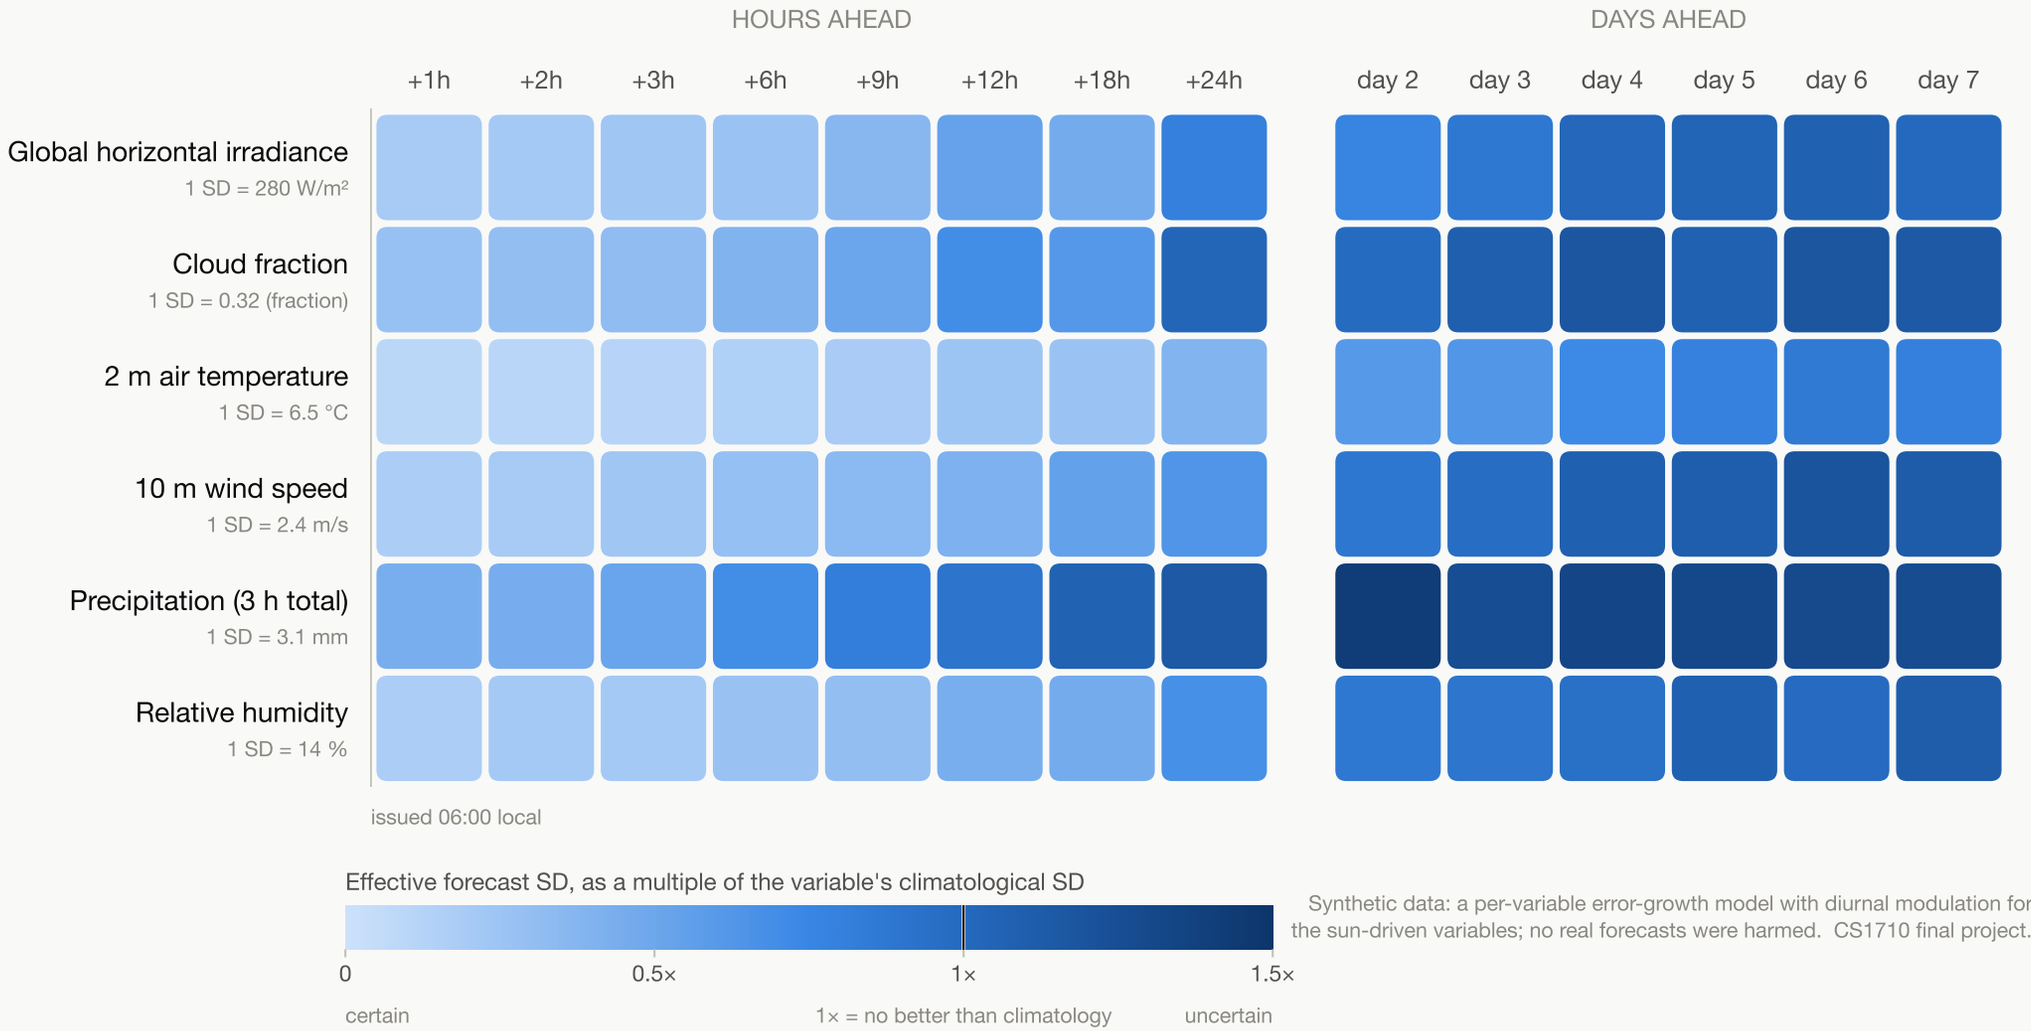
How uncertain is the forecast, and when?

Each cell is one forecast variable at one lead time, shaded by its effective standard deviation (ensemble spread and systematic bias combined) in units of that variable's own climatological SD. Darker = less certain. Hourly steps through the first day, then daily steps out to a week.



Synthetic data: a per-variable error-growth model with diurnal modulation for the sun-driven variables; no real forecasts were harmed. CS1710 final project.
